# 1 Introduction

## 2 Preliminaries

### 2.1 Büchi Automaton

Büchi automaton is a theoretical finite state machine, that decides which infinitely long words ( $\omega$ -words) are recognized by (given?) language. Let us define transition-based Buchi Automaton (TBA).

TBA is a quintuple  $A = (\Sigma, Q, q_0, \Delta, \Gamma)$ . An alphabet is a set of letters.  $\Sigma$  is a finite alphabet recognized by A.  $Q$  is a finite set of states of A,  $q_0 \in Q$  is called the initial state of A. Transitions of A directionally connect 2 states inside  $Q$  with a letter from alphabet  $\Sigma$ . We write the set of transitions as  $\Delta \subseteq Q \times \Sigma \times Q$ . Subset of the transitions  $\Gamma \subseteq \Delta$  are accepting transitions.

Now our goal is to define language  $L_A$ . It allows us to specify which  $\omega$ -words are accepted or rejected by the automaton. To achieve our goal we will need to define run on automaton A.

Run  $r \in \Delta^\omega$  on A is an infinite sequence of transitions such that for the first transition  $r_0 = (q'_0, a, q''_0) \in r$  holds that  $q'_0$  is the initial state of A and for each subsequent state  $r_i = (q'_i, a, q''_i)$  holds that  $q'_i = q''_{i-1}$ . A run of TBA is accepting, iff it contains infinitely many accepting transitions.

Finally we can define the language recognized by an automaton  $L_A \in \Sigma^\omega$ . An  $\omega$ -word  $x \in \Sigma^\omega$  belongs to  $L_A$  if there exists an accepting run  $r$  in the automaton A for the word  $x$ .

### 2.2 TGBA

## 3 To Delete Chapter

### 3.1 Büchi Automaton

A nondeterministic Büchi automaton (BA) is a tuple  $A = (\Sigma, Q, q_0, \Delta, \Gamma)$ , where

- $\Sigma$  is a finite alphabet
- $Q$  is finite set of states
- $q_0 \in Q$  is the initial state
- $\Delta \subseteq Q \times \Sigma \times Q$  are transitions
- $\Gamma \subseteq \Delta$  are accepting transitions

**run** A run  $r$  of  $A$  on  $w \in \Sigma^\omega$  is an  $\omega$ -word  $r_0, w_0, r_1, w_1, \dots$  in  $(Q \times \Sigma)^\omega$  such that  $r_0 = q_0 \wedge \forall i > 0, (r_{i-1}, w_{i-1}, r_i) \in \Delta$

**inf(r)** We write  $\text{inf}(r) \subseteq \Delta$  for the set of transitions that appear infinitely often in the run  $r$ .

**accepting run** A run  $r$  is accepting if  $\text{inf}(r) \cap \Gamma \neq \emptyset$

**language** The language  $L_A \subseteq \Sigma^\omega$  is recognized by  $A$ .  
 $\forall w \in L_A \exists r$  on  $w$  such that  $r$  is accepting.

**$\omega$ -regular language** A language is  $\omega$ -regular if it is accepted by BA.

**deterministic automaton**  $A = (\Sigma, Q, q_0, \Delta, \Gamma)$  is deterministic if  
 $(q, \rho, q'), (q, \rho, q'') \in \Delta \implies q' = q''$

**complete automaton**  $A$  is complete if,  $\forall w \in \Sigma, \forall q \in Q, \exists (q, w, q') \in \Delta$ . A word in  $\Sigma^\omega$  has exactly one run in a deterministic, complete automaton.

## 3.2 Markov Decision Processes

A Markov decision process (MDP)  $M$  is a tuple  $(S, A, T, \Sigma, L)$ , where

- $S$  is a finite set of states
- $A$  is a finite set of actions
- $T : S \times A \rightarrow D(S)$ , where  $D(S)$  is set of probability distributions over  $S$ , is the probabilistic transition (partial) function
- $\Sigma$  is an alphabet
- $L : S \times A \times S \rightarrow \Sigma$  is the labeling function of the set of transitions. For a state  $s \in S$ ,  $A(s)$  denotes the set of actions available in  $s$ .

**run** A run of  $M$  is an  $\omega$ -word  $s_0, a_1, \dots \in A = S \times (A \times S)^\omega$  such that  $Pr(s_{i+1}|s_i, a_{i+1}) > 0$  for all  $i \geq 0$ . A finite run is a finite such sequence.

**labeled run** We define labeled run as  $L(r) = L(s_0, a_1, s_1), L(s_1, a_2, s_2), \dots \in \Sigma^\omega$ .

**paths** We write  $\Omega(M)(Paths(M))$  for the set of runs (finite runs) of  $M$  and  $\Omega_s(M)(Paths_s(M))$  for the set of runs (finite runs) of  $M$  starting from state  $s$ . When the MDP is clear from the context we drop the argument  $M$ .

**strategy** A strategy in  $M$  is a function  $\mu : Paths \rightarrow D(A)$  such that  $supp(\mu(r)) \subseteq A(last(r))$ , where  $supp(d)$  is the support of  $d$  and  $last(r)$  is the last state of  $r$ . Let  $\Omega_\mu^M$  denote the subset of runs  $\Omega^M$  that correspond to strategy  $\mu$  and initial state  $s$ . Let  $\Pi_M$  be the set of all strategies.

**pure strategy** We say that a strategy  $\mu$  is pure if  $\mu(r)$  is a point distribution for all runs  $r \in Paths$ .

**behavior** The behavior of an MDP  $M$  under a strategy  $\mu$  with starting state  $s$  is defined on a probability space  $(\Omega_s^\mu, F_s^\mu, Pr_s^\mu)$  over the set of infinite runs of  $\mu$  from  $s$ .

### 3.3 [WIP]Good-for-MDP (GFM) Automata

Given an MDP  $M$  and an automaton  $A = (\Sigma, Q, q_0, \Delta, \Gamma)$ , we want to compute an optimal strategy satisfying the objective that the run of  $M$  is in the language of  $A$ .

#### semantic satisfaction probability for given automaton and strategy

We define the semantic satisfaction probability for  $A$  and strategy  $\mu$  from state  $s$  as:

$$PSem_A^M(s, \mu) = Pr_s^\mu \{r \in \Omega_s^\mu : L(r) \in L_A\}$$

#### semantic satisfaction probability for given automaton

$$PSem_A^M(s) = \sup_{\mu \in \Pi_M} PSem_A^M(s, \mu)$$

**syntactic variant of the acceptance condition** When using automata for given analysis of MDPs, we need a syntactic variant of the acceptance condition.

**product of MDP and automaton** Given an MDP  $M = (S, A, T, \Sigma, L)$  with initial state  $s_0 \in S$  and automaton  $A = (\Sigma, Q, q_0, \Delta, \Gamma)$ , the product  $M \times A = (S \times Q, (s_0, q_0), A \times Q, T^\times, \Gamma^\times)$  is an MDP augmented with an initial state  $s_0 \in S$  and accepting transitions  $\Gamma^\times$ . The (partial) function  $T^\times : (S \times Q) \times (A \times Q) \rightarrow D(S \times Q)$  is defined by

$$T^\times((s, q), (a, q'))((s', q')) = \begin{cases} T(s, a)(s') & \text{if } (q, L(s, a, s'), q^1) \in \Delta \\ \text{undefined} & \text{otherwise} \end{cases}$$

**GFM Automata** An automaton  $A$  is good for MDPs if, for all MDPs  $M$ ,  $PSYN_A^M(s_0) = PSEM_A^M(s_0)$  holds, where  $s_0$  is the initial state of  $M$ .

### **3.4 to be defined**

$\omega$ -word?, point distribution?, what is  $F_s^\mu$  in 'pure strategy' paragraph?, TGBA, describe Semi-deterministic as I am going to compare them with SBA
